## Office Action Summary

Application No.

10/081,955

Applicant(s)

SEIDEL ET AL.

Examiner

Carla Myers

Art Unit

1634

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --  
Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If the period for reply specified above is less than thirty (30) days, a reply within the statutory minimum of thirty (30) days will be considered timely.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

### Status

- 1) ☒ Responsive to communication(s) filed on 29 August 2003.
- 2a) ☐ This action is **FINAL**. 2b) ☒ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

### Disposition of Claims

- 4) ☒ Claim(s) 124-141 is/are pending in the application.
- 4a) Of the above claim(s) \_\_\_\_\_ is/are withdrawn from consideration.
- 5) ☐ Claim(s) \_\_\_\_\_ is/are allowed.
- 6) ☒ Claim(s) 124-141 is/are rejected.
- 7) ☐ Claim(s) \_\_\_\_\_ is/are objected to.
- 8) ☐ Claim(s) \_\_\_\_\_ are subject to restriction and/or election requirement.

### Application Papers

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☒ The drawing(s) filed on 02 February 2002 is/are: a) ☒ accepted or b) ☐ objected to by the Examiner.  
Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).  
Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

### Priority under 35 U.S.C. § 119

- 12) ☐ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☐ All b) ☐ Some \* c) ☐ None of:
1. ☐ Certified copies of the priority documents have been received.
2. ☐ Certified copies of the priority documents have been received in Application No. \_\_\_\_\_.
3. ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).
- \* See the attached detailed Office action for a list of the certified copies not received.

### Attachment(s)

- 1) ☒ Notice of References Cited (PTO-892)
- 2) ☐ Notice of Draftsperson's Patent Drawing Review (PTO-948)
- 3) ☒ Information Disclosure Statement(s) (PTO-1449 or PTO/SB/08)  
Paper No(s)/Mail Date 8/29/03, 10/3/02
- 4) ☐ Interview Summary (PTO-413)  
Paper No(s)/Mail Date. \_\_\_\_\_
- 5) ☐ Notice of Informal Patent Application (PTO-152)
- 6) ☐ Other: \_\_\_\_\_

## **DETAILED ACTION**

### **Claim Objections**

1. Claims 126, 133 and 140 are objected to because of the following informalities:

In claim 126, "a an ovulatory" should read "an ovulatory".

In claim 140, "herpes" should read "HEPES".

In claim 133, a "." should be inserted following "contains".

### **Claim Rejections - 35 USC § 112**

2. The following is a quotation of the first paragraph of 35 U.S.C. 112:

The specification shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same and shall set forth the best mode contemplated by the inventor of carrying out his invention.

Claims 124-141 are rejected under 35 U.S.C. 112, first paragraph, because the specification, while being enabling for methods of producing bovine offspring wherein the methods comprise collecting semen from a bovine, staining the sperm cells in the semen, sorting the sperm by sex chromosomes using a MoFlo flow cytometer / cell sorter at 50 psi using 2.9% Na Citrate as a sheath fluid, collecting the sperm at approximately 500 live sperm/second into tubes containing Cornell Universal Extender (CEU) with 20% egg yolk, and using, within 5-9 hours post-sorting,  $3 \times 10^5$  live, cooled sperm to inseminate bovine that were previously synchronized with prostaglandin F-2 alpha at 12 day intervals, wherein said method results in pregnancy rates of about 80% of controls inseminated using  $15.6 \times 10^6$  motile non-sorted/unsexed sperm (see page 25 of the specification), does not reasonably provide enablement for methods of producing any human or nonhuman mammal wherein said methods comprise sorting

Art Unit: 1634

sperm cells by any means based on the sex characteristic, generating an insemination sample having a low number of sperm capable of fertilizing at least one egg within a female at success levels comparable to a typical insemination dosage, inserting any portion of the insemination sample into a female mammal that has been superovulated, fertilizing at least one egg within the female and producing a mammal of a desired sex. The specification does not enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the invention commensurate in scope with these claims.

The following factors have been considered in formulating this rejection (*In re Wands*, 858F.2d 731, 8 USPQ2d 1400 (Fed. Cir. 1988): the breadth of the claims, the nature of the invention, the state of the prior art, the relative skill of those in the art, the predictability or unpredictability of the art, the amount of direction or guidance presented, the presence or absence of working examples of the invention and the quantity of experimentation necessary.

The claims are broadly drawn to for methods of producing any nonhuman mammal or a human mammal wherein said methods comprise superovulating a mammal, generating an insemination sample having a low number of sperm capable of fertilizing a plurality of eggs within said mammal, fertilizing the eggs at success levels comparable to a typical insemination dosage, inserting any portion of the insemination sample into the female, and producing a mammal. The claims further include staining the sperm and sorting the sperm according to a sex characteristic at sorting rates of 500 and 2000 sorts per second. The claims also require producing at least two embryos

Art Unit: 1634

from the female mammal. The claims do not specify the total number of sperm used for the insemination procedure. Rather, the claims allow for a step of establishing an insemination sample with a low number of sperm and then using any portion of this sample to inseminate a female mammal. It is unclear as to what portion of the sample would be used in the insemination process and in view of the comprising language, it is unclear as to whether additional undefined samples may also be used for the insemination process.

Case law has established that “(t)o be enabling, the specification of a patent must teach those skilled in the art how to make and use the full scope of the claimed invention without ‘undue experimentation.’” *In re Wright* 990 F.2d 1557, 1561. *In re Fisher*, 427 F.2d 833, 839, 166 USPQ 18, 24 (CCPA 1970) it was determined that “(t)he scope of the claims must bear a reasonable correlation to the scope of enablement provided by the specification to persons of ordinary skill in the art”. Furthermore, the Court in *Genetech Inc. v Novo Nordisk* 42 USPQ2d 1001 held that “(I)t is the specification, not the knowledge of one skilled in the art that must supply the novel aspects of the invention in order to constitute adequate enablement”. In the instant case, the specification has not adequately taught one of skill in the art how to practice methods of producing at least two embryos and methods for producing any mammal of a desired sex using a low number of sorted sperm and achieving success rates comparable to that obtained with a “typical insemination dosage” for the following reasons.

The claims broadly encompass methods for producing a human or any nonhuman mammal using a low number of separated sperm while still achieving success rates comparable to that obtained with a typical insemination sample. However, the specification provides only one specific example in which such a method has been accomplished. In particular, example 1, set forth on 25 of the specification, describes a method of using a "low dose" of sex sorted sperm for artificial insemination of a bovine. The method requires collecting a sperm sample from a bovine, staining the sperm cells in the semen, sorting the sperm by sex chromosomes using a MoFlo flow cytometer / cell sorter at 50 psi using 2.9% Na Citrate as a sheath fluid, collecting the sperm at approximately 500 live sperm/second into tubes containing Cornell Universal Extender (CEU) with 20% egg yolk, cooling the sperm sample, and using  $3 \times 10^5$  live, cooled sperm to inseminate bovine that were previously synchronized with prostaglandin F-2 alpha at 12 day intervals. The sorted sperm were used for insemination within 5-9 hours after sorting and the method resulted in pregnancy rates of about 80% of controls inseminated using  $15.6 \times 10^6$  motile non-sorted/unsexed sperm. Example 3 of the specification also describes a method of using sex-sorted, unfrozen sperm for insemination purposes. This example states that in one instance insemination with  $1-2 \times 10^5$  sperm in .1 ml resulted in pregnancy rates of 41% at 8 weeks and in pregnancy rates of 50% at 8 weeks when insemination was performed within 10 hours of the end of sorting. These examples do not provide any information as to the number of embryos that were produced in the female mammal and particularly do not teach that at least two embryos were successfully produced in each mammal.

The specification clearly sets forth the unpredictability in the art of using sex sorted sperm for artificial insemination and particularly of using low-dosages of sex sorted sperm for AI. There are an extensive number of variables which effect the viability of the sperm, the success rate of AI, the ability to fertilize multiple eggs, and the pregnancy success rate. For example, at page 3, the specification states that "the sperm are time-critical cells. They lose their effectiveness the longer they remain unused." In Example 3, the specification teaches that when 38 heifers were inseminated about 22 hours post-sorting, none of the heifers were pregnant 8 weeks after insemination. When inseminations were done 18-29 hours post-sorting, of 33 heifers only 1 remained pregnant at 8 weeks. Additionally, when inseminations were performed 17 to 24 hours post-sorting, only 1 of 7 inseminated females was pregnant at 8 weeks. The specification also emphasizes the unpredictability of using low dosage sex sorted sperm for insemination. The specification defines "low dose" as including levels of 10% to 50% of typical, non-sorted insemination samples. However, the specification exemplifies using low dosages of sex sorted sperm only with bovine animals wherein the dosage is a minimum of  $1-3 \times 10^5$  live, cooled sperm used within 10 hours of sorting. Given the unpredictability in using low dosages of sex sorted sperm for insemination purposes, it is highly unpredictable as to the quantity of bovine sperm or other mammalian sperm that would acceptable to allow for fertilization success rates comparable to those obtained with high dosages of unsorted semen.

The specification (at page 27) also teaches that the handling of the sample post-sorting significantly effects the success of the insemination process. When insemination

samples were shipped at ambient temperature, 0 out of 10 females became pregnant. Only when the sperm was cooled to 5C during shipping, was insemination effective.

At page 3-4, the specification discusses additional factors which hinder the use of sex-sorted sperm. It is stated that "the process through normal flow cytometer techniques may, in fact, be unacceptable for cytometric sorting of sperm cells in certain applications. The sensitivities range from dilution problems and the flow cytometers inherent need to isolate and distinguish each cell individually as well as the pressure and other stresses which typical flow cytometry has, prior to the present invention imposed upon the cells or other substances that it was sorting. This may also represent a unique factor for sperm cells because it appears that even though the sperm cell may appear to pass through the flow cytometer and be sorted with no visually discernable side-effects, in fact, the cells themselves may have been stressed to the point that they perform less optimally in the insemination process." While this passage appears to state that these problems occurred only prior to the present invention, the specification and claims do not recite any particular advancements which allow for the ordinary artisan to overcome each of these problems when sorting sex from any organism, using any means for sensing a sex characteristic, any means for separating the sperm, any means for collecting the sperm, any means for storing and transporting the sperm, any low dosage of sperm and any means of artificial insemination. The specification teaches that the sorting rate and pressure used to run the flow cytometer may significantly effect sperm viability. However, the majority of the claims allow for the use of any type of apparatus to sense the sex characteristic and to separate the sperm cells based on the

Art Unit: 1634

sex characteristic. The specification does not provide sufficient guidance to enable the skilled artisan to use any apparatus under any conditions, and particularly under any conditions of pressure or sort rate, to generate insemination samples that achieve fertilization rates comparable to those obtained with unsexed, unsorted sperm cells.

The specification further teaches that the selection of a sheath fluid greatly influences the viability of the sperm cells. For instance, at page 12, the specification teaches that "the stress imposed by handling of the cells within the flow cytometer appears significant for this application...For instance, while it has been known to utilize fluids having a proper pH factor or osmoality, the present invention recognizes that there may be certain chemical compositions to which the cells may be hyper-responsive. These hyper-responsive chemical compositions may naturally vary based upon the cells or even the prior handling of the cells." The specification goes on to teach a specific citrate-based sheath fluid for sorting bovine cells and a HEPES-based sheath fluid for sorting equine cells. However, the specification does not teach chemical compositions that are suitable for sorting other types of mammalian sperm. As set forth in the specification, a sperm cells response to a chemical will vary depending on the type of chemical, source of sperm cell and previous handling of the sperm cells. The identity of the chemicals that cause stress to sperm cells from other bovine, equine and other mammals can only be determined through experimentation. There is no predictable means for determining a priori which sheath fluids will impose minimal stress on the sperm cells and allow for the sorting of sperm cells to generate an insemination sample that can be used to fertilize eggs at the same success level as a

Art Unit: 1634

typical insemination sample. In particular, with respect to claims 140 and 141, the specification has not enabled using any HEPES sheath fluid for the sorting of any type of sperm cell. The specification has stated that it is unexpected that HEPES-based HBGM3 solution was effective as a sheath fluid during the sorting of equine sperm. The specification has not taught that this solution can be used with other sperm cells or that other HEPES solutions can be used with equine or other types of sperm cells. In view of the unpredictable effects that chemical compositions may have on the viability of sperm cells, undue experimentation would be required to practice the methods of claims 140 and 141 as they are broadly claimed.

Other factors which influence sperm viability include different aspects of the collection process. At page 15, the specification teaches that "it may be important that the container which makes up the collector be properly sized so that it acts as some means of avoiding an impact between the cells and the container itself." The specification also discusses the criticality of selecting a proper collection fluid in order to reduce stress to the sperm cells.

The specification further teaches that the dilution process may effect the success rate of the insemination process. At page 21 of the specification, it is stated that "It has been discovered that dilution may create an effect upon the sperm cell's viability and so it may be appropriate to avoid too large a level of dilution by providing a smaller sample." However, the specification does not teach what would constitute an appropriate level of dilution or appropriate type of dilution solution for diluting the sperm of the wide array of non-bovine mammals encompassed by the claims and does not

provide sufficient guidance for selecting alternative dilution levels and solutions for non-bovine sperm samples. The unpredictability surrounding the insemination process is highlighted by the passage at page 22: "The utilization of embryo transfer equipment may be used because there may be high sensitivity of the uterine wall for such low dose, sexed inseminations." Yet, the specification does not clarify which mammals require or do not require the utilization of embryo transfer equipment.

With respect to claim 134, the step of staining the sperm cells is also known to be critical in influencing the viability of the sperm and effectiveness of the sorting procedure to obtain viable sperm. Responsiveness to stain also varies depending on the type of stain. The specification (page 20) teaches that higher amounts of stain might "to some extent" provide better results. The specification teaches using a solution of 38uM Hoeschst 33342 stain. The specification does not specifically exemplify improved results using this concentration of stain. Claim 134 allows for the use of any stain, as long as it is present at a concentration of 38uM. However, the specification does not teach any stains other than Hoeschst 3342 that can be used at this concentration. In view of the unpredictability as to how a stain and the concentration of stain will effect the viability of sperm cells and the sorting process, undue experimentation would be required to practice the claimed invention using any stain at a concentration of 38uM.

Additionally, the ability to apply the claimed sorting and insemination method to non-bovine mammals and particularly to humans is highly unpredictable. The specification does not provide any specific examples of using low doses of sex sorted sperm for insemination in non-bovine animals. Given the variability in sperm viability in

Art Unit: 1634

different species and the variability in sorting success and insemination success in different species, it is highly unpredictable as to whether the results obtained with bovine can be extended to other species. The unpredictability in applying the claimed invention to non-bovine mammals is emphasized by the teachings in the specification. At page 4, the specification states that "artificial insemination with a high success rate is one of a statistical nature in which a multitude of factors seem to interplay. Thus, solutions proposed to some degree involve a combination of factors which, when thoroughly statistically studied, will be shown to be necessary either in isolation or in combination with other factors. Such a determination is further compounded by the fact that **the results vary by species** and may be difficult to ascertain due to the fact that testing and statistical sampling on a large enough database is not likely to be worth the effort at the initial stages." Yet, the specification does not provide any specific guidance as to what particular combination of factors/conditions would be required to obtain comparable success rates in non-bovine, non-human mammals. Additionally, the teachings of Johnson (cited in the IDS; Journal of Reproduction and Fertility, 1997) highlight the unpredictability of using low dosage sex sorted sperm in other mammals. Specifically, Johnson (page 262) teaches that "It is unlikely that the technology for small numbers of spermatozoa from cattle will be directly applied to swine because of the anatomy of the pig uterus which provides an impediment to small numbers of spermatozoa." The specification does not particularly address this limitation and does not provide any particular guidance as to how to overcome this obstacle when inseminating pigs or other mammals having a uterus of similar anatomy. Furthermore,

Art Unit: 1634

Cran (Theriogenology, (January 1997) 47:267; cited in the IDS) also emphasizes the unpredictability of using low doses and/or sex sorted semen for insemination. Cran teaches that pregnancy rates of lambs were low when sex sorted semen was used for insemination. In one study, 0 of 18 ewes inseminated with low doses of X sperm lambed, while 5/12 inseminated with unsorted sperm produced lambs. In a second study, none of 5 ewes inseminated with low dose Y sperm lambed; 4/25 inseminated with low dose X sperm lambed; and 2/30 inseminated with unsorted low dose sperm lambed. Cran states that the low pregnancy rates may be due to a combination of delay between semen collection and insemination, asynchrony between insemination and ovulation, semen dose and the onset of seasonal anestrus. However, the specification and prior art do not provide any specific guidance as to how to modify the method of Cran so as to predictably generate a method in which low doses of ram semen can be used to produce fertilization rates equivalent to that obtained when using high doses of unsexed sperm. It is unpredictable as to how the methodology would need to be modified in order to effectively perform low dosage AI with sex sorted sperm in other mammals, including humans. The teachings in the specification regarding bovine do not provide sufficient guidance to enable the use of this technology in other mammals because it is unclear as to how the viability of the sperm will be effected by the rate and pressure of the sorting process, the sheath fluid used for the sorting process, the collection fluid and collection container, the dilution process, the freezing process, and the type of insemination procedure.

Accordingly, the specification emphasizes the unpredictability in the art of using low dose sex-sorted sperm for AI and teaches that a multitude of factors interact in undefined ways to influence the viability of the sorted sperm and the success rate of insemination. However, the specification teaches only one particular set of conditions – i.e., the conditions set forth in Example 1 - that were shown to be effective for achieving success rates with low dose sex-sorted sperm comparable to success rates achieved using a typical high dosage, nonsorted insemination sample. Sufficient guidance is not provided in the specification as to how to modify the conditions set forth in Example 1 and maintain a success rate that is about 80% of the success rate achieved with typical insemination samples.

Additionally, sufficient guidance is not provided in the specification as to how to apply the methodology used with bovine to all other mammals. The claims encompass producing multiple embryos from any female mammal and thereby include producing multiple embryos from humans, pandas, elephants, whales etc. The genus of mammals is significantly large and includes a vast multitude of animals whose sperm has not been previously studied for its ability to be sorted, for its sensitivity to chemicals and the sorting process, for its sensitivity to handling and freezing processes or for its ability to be used for insemination purposes. For example, Fugger (1999; cited in the IDS) teaches that the ability to effectively sort sperm cells varies with species as a function of the shape of the sperm and the magnitude of difference in DNA content between X and Y chromosomes. Additionally, Johnson (1992, page 13; cited in the IDS) teach the difference in DNA content between X and y chromosome bearing sperm for several

Art Unit: 1634

organisms, including turkey (0% difference), human (2.9% difference) and rabbit (3% difference). Johnson also reports that rabbit sperm were sorted to purities of 86% for X-chromosome bearing sperm and 81% for Y-chromosome bearing sperm. The specification has not taught that a representative number of non-human mammals have sperm of an acceptable shape and having an acceptable difference in the DNA content of their X and Y chromosomes to allow for the sorting of sperm at levels of more than 60, 70, 80 or 90%. There are no teachings in the prior art as to how to overcome the problems associated with a lack of difference in the DNA content between X and Y-chromosome bearing sperm or the challenges imposed by the shape, morphology and heterogeneity of sperm.

For the reasons set forth above and in view of the high level of unpredictability in the art and the lack of specific guidance provided in the specification, undue experimentation would be required to practice the invention as it is broadly claimed.

3. Claims 124-141 are rejected under 35 U.S.C. 112, second paragraph, as being indefinite for failing to particularly point out and distinctly claim the subject matter which applicant regards as the invention.

Claims 124-141 are indefinite over the recitation of "low number of separated non-human sperm." The term "low" is a relative term which renders the claim indefinite. The term "low" is not clearly defined by the claim and the specification does not provide a standard for ascertaining the requisite number of sperm which would be considered low for any mammal. The specification (page 19) states that "By the term 'low dose' it is meant that the dosage of sperm utilized in the insemination event are less than one-half

or preferably even less than about 10% of the typical number of sperm provided in a typical artificial insemination event." However, the specification does not clearly set forth what is intended to constitute a typical artificial insemination event. The specification also states that with respect to bovine, a low dose may be 500,000 sperm or 300,000 sperm or lower. For equine, it is stated that a low dose may be 25, 10, 5 or even one million sperm. Clearly, there is a significant degree of variability surrounding what might constitute "low dose" (e.g., 25 million versus 1 million) and there is no specific teaching in the specification or art as to what is generally accepted by practitioners as a "low dose" with respect to bovine, equine and other members of the broadly claimed genus of nonhuman mammals. Accordingly, one of ordinary skill in the art would not be reasonably apprised of the scope of the invention.

Claims 124-141 are indefinite over the recitation of "success levels statistically comparable to a typical insemination dosage." There is no fixed definition in the art for what constitutes a typical insemination dosage for all mammals and this phrase has not been clearly defined in the specification. Further, it is unclear as to what is considered to constitute "comparable levels." For example, it is unclear as to whether 60% or 70% or 80% or 90% or 95% of the control success rate would be considered to be a comparable level. Accordingly, one could not determine the meets and bounds of the claimed invention.

Claims 126-129 are indefinite and vague over the recitation of "between any of days 2 and 18" because the claims do not set forth how one determines that it is day 2 or 18. The claims do not clarify whether days 2 and 18 are determined with respect to,

for example, any random date, the date the insemination sample is established, superovulation, or the date of the estrous cycle.

Claims 127-129 are indefinite over the recitation of "said estrous manipulation system" because this phrase lacks proper antecedent basis.

Claims 136-141 are indefinite and confusing over the recitation of "producing an animal of a desired sex in accordance with the process as described in claim 135." Claim 135 is drawn to a method of making multiple embryos, but does not include a step of producing an animal. It is unclear as to what is intended to be the relationship between claims 135 and claims 136-141 and it is unclear as to how the recitations in claims 136-141 further limit the method of claim 135. Claims 136-141 do not clarify how the step of making multiple embryos results in the production of an animal. It is also unclear as to what is meant by the term "in accordance." That is, it is unclear as to whether claims 136-141 require performing all of the method steps of claim 135 or only some of the method steps of claim 135 or a modified version of the method steps of claim 35. Further, claim 135 requires the fertilization of a mammal, not of any animal in general and thereby it is further unclear as to how claim 136 is intended to be further limiting from claim 135.

### ***Claim Rejections - 35 USC § 103***

6. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the

invention was made to a person having ordinary skill in the art to which said subject matter pertains.

Patentability shall not be negated by the manner in which the invention was made.

This application currently names joint inventors. In considering patentability of the claims under 35 U.S.C. 103(a), the examiner presumes that the subject matter of the various claims was commonly owned at the time any inventions covered therein were made absent any evidence to the contrary. Applicant is advised of the obligation under 37 CFR 1.56 to point out the inventor and invention dates of each claim that was not commonly owned at the time a later invention was made in order for the examiner to consider the applicability of 35 U.S.C. 103 and potential 35 U.S.C. 102(f) or (g) prior art under 35 U.S.C. 103(a).

Claims 124-127 and 130-136 are rejected under 35 U.S.C. 103(a) as being unpatentable over Seidel (Theriogenology, January 1996; cited in the IDS) in view of Brink (Theriogenology (1994) 41: 168).

Seidel teaches methods for making bovine mammals comprising sorting stained sperm cells by DNA content using flow cytometry wherein the sperm cells are sorted for sex characteristics to purity rates of about 90%, establishing an insemination sample, inserting a low dosage ( $1-2 \times 10^5$  in .1 ml) of sorted sperm cells into the uterine horns of the female bovine after the onset of estrus; and fertilizing the eggs of the bovine so as to produce at least one offspring of the desired sex. Seidel teaches that 11 of 22 females inseminated with sperm cooled to 5C during shipping were pregnant at 8 weeks. In view of the teachings in the specification, this is considered to be a success level comparable to a typical insemination dosage. The sperm were deposited deep in the uterine horn ipsilateral to the ovary with the largest follicle being determined by ultrasound. Seidel does not teach superovulating the females prior to insemination.

However, Brink (1994) teaches methods for stimulating superovulation in cows. In the method of Brink, cows are treated twice a day at 12 hour intervals with injections

Art Unit: 1634

of 6, 6, 4, 4, 2, 2, 2, and 2 mg FSH and given three dosages of prostaglandin of 25 mg and 12.5 mg PGF-2-alpha on days 6 and 7, respectively, of FSH treatments. The superovulation treatment is initiated starting between days 9 and 14 of the estrous cycle.

It would have been obvious to one of ordinary skill in the art at the time the invention was made to have modified the method of Seidel so as to performed the surgical insemination procedure on females that were superovulated and synchronized using the FSH/PGF-2-alpha treatment methods as disclosed by Brink in order to have achieved the benefit of providing a more effective and convenient means of insemination since the females could then be inseminated at the most optimal time during estrous and the timing of the insemination procedure could be scheduled to correspond with the collection and sorting of sperm.

7. Claims 128 and 129 are rejected under 35 U.S.C. 103(a) as being unpatentable over Seidel (1996) in view of Brink and further in view of Seidel (1995; cited in the IDS).

The teachings of Seidel (1996) and Brink are presented above. In particular, Seidel (1996) teaches that the sperm were deposited deep in the uterine horn ipsilateral to the ovary with the largest follicle being determined by ultrasound. The combined references do not teach insemination both ipsi and contra-lateral within the uterine horns.

However, Seidel (1995) teaches ipsilateral and contra-lateral insemination of low dose semen into females. The reference teaches that pregnancy rates were nearly identical for ipsilateral and contra-lateral insemination.

Accordingly, it would have been obvious to one of ordinary skill in the art at the time the invention was made to have modified the method of Seidel (1996) so as to have performed the insemination procedure by inserting the semen both ipsi and contra-lateral into the uterine horns because this would have provided an equally effective means for inseminating female bovine.

8. Claims 137 and 138 are rejected under 35 U.S.C. 103(a) as being unpatentable over Seidel (1996) in view of Brink (1994) and further in view of Rens (U.S. Patent No. 5,985,216).

The teachings of Seidel (1996) and Brink are presented above. The combined references not specify the rate of sorting and specifically does not teach sorting sperm at rates of 500 or 1200 sorts/second.

Rens teaches a method of high speed flow cytometry for sorting sperm. In the method of Rens (see columns 4-6), a sample of sperm is obtained from a male mammal, the sperm is stained with Hoeschst 33342 dye in order to distinguish between viable and nonviable sperm (column 5, lines 4-10), the sperm are sorted in a high speed flow cytometer using a nozzle that forms a stable droplet containing each individual sperm cell (column 2, lines 23-32), the sperm are sorted according to their sex characteristics and isolated populations of X- and Y-chromosome bearing sperm are collected. Rens teaches sampling rates of 500 sperm/second and 2000 sperm/second (column 6). Further, the nozzle allowed for sample rates up to at least 15,000 sperm/sec (column 4, lines 29-31). Rens states that the "high level of performance is beneficial for efficient sperm sorting." Accordingly, it would have been obvious to one of ordinary skill

in the art at the time the invention was made to have modified the method of Seidel so as to have used sorting rates of about 500 sperm/sec or 1200 sperm/second in order to have allowed for the faster sorting of sperm so as to have provided adequate quantities of sex-sorted samples that could be used for the insemination process.

9 . Claims 124-136 are rejected under 35 U.S.C. 103(a) as being unpatentable over Seidel (Theriogenology (1997) 48:1255-1264; cited in the IDS) In view of Brink (Theriogenology (1994) 41: 168).

Seidel (pages 1257-1258 – “Experiment 2”) teaches methods for making bovine mammals comprising sorting sperm cells according to sex using flow cytometry wherein the sperm cells are sorted to purity rates of about 90%, establishing an insemination sample, inserting a low dosage ( $1-2 \times 10^5$  in .1 ml) of sorted sperm cells into the uterine horns of the female bovine after the onset of estrus; and fertilizing the eggs of the bovine so as to produce at least one offspring of the desired sex. Seidel (Table 1) teaches that 50% of the females inseminated with  $2.5 \times 10^5$  sperm became pregnant. In view of the teachings in the specification, this is considered to be a success level comparable to a typical insemination dosage. The sperm were deposited deep in the uterine horn ipsilateral to the ovary with the largest follicle being determined by ultrasound. Inseminations were performed within 9 to 29 hours after sorting and thereby Seidel teaches inseminating the females within 10 hours of sorting. With respect to claim 129, Seidel teaches inseminating females that were detected to be in estrous 24 hours earlier. Seidel teaches that heifers are treated twice at 12-day intervals with 25

mg PGF-2-alpha to synchronize estrous. Seidel does not teach creating superovulation in the mammals by treating them with FSH.

Brink teaches methods for stimulating superovulation in cows. In the method of Brink, cows are treated twice a day at 12 hour intervals with injections of 6, 6, 4, 4, 2, 2, 2, and 2 mg FSH and given three dosages of prostaglandin of 25 mg and 12.5 mg PGF-2-alpha on days 6 and 7, respectively, of FSH treatments. The superovulation treatment is initiated starting between days 9 and 14 of the estrous cycle.

It would have been obvious to one of ordinary skill in the art at the time the invention was made to have modified the method of Seidel so as to performed the surgical insemination procedure on females that were superovulated and synchronized using the FSH/PGF-2-alpha treatment methods as disclosed by Brink in order to have achieved the benefit of providing a more effective and convenient means of insemination since the females could then be inseminated at the most optimal time during estrous and the timing of the insemination procedure could be scheduled to correspond with the collection and sorting of sperm.

With respect to claims 128 and 129, Seidel (1997) teaches that the sperm were deposited deep in the uterine horn ipsilateral or contra-lateral to the ovary with the largest follicle being determined by ultrasound. Seidel does not teach insemination both ipsi and contra-lateral within the uterine horns. However, Seidel does teach ipsilateral and contra-lateral insemination of low dose semen into females. Additionally, Seidel teaches that pregnancy rates were nearly identical for ipsilateral and contra-lateral insemination.

Accordingly, it would have been obvious to one of ordinary skill in the art at the time the invention was made to have modified the method of Seidel so as to have performed the insemination procedure by inserting the semen both ipsi and contralateral into the uterine horns because this would have provided an equally effective means for inseminating female bovine.

10. Claims 137 and 138 are rejected under 35 U.S.C. 103(a) as being unpatentable over Seidel (1997) in view of Brink and further in view of Rens (U.S. Patent No. 5,985,216).

The teachings of Seidel (1997) and Brink are presented above. The combined references not teach sorting sperm at rates of 500 or 1200 sorts/second.

Rens teaches a method of high speed flow cytometry for sorting sperm. In the method of Rens (see columns 4-6), a sample of sperm is obtained from a male mammal, the sperm is stained with Hoeschst 33342 dye in order to distinguish between viable and nonviable sperm (column 5, lines 4-10), the sperm are sorted in a high speed flow cytometer using a nozzle that forms a stable droplet containing each individual sperm cell (column 2, lines 23-32), the sperm are sorted according to their sex characteristics and isolated populations of X- and Y-chromosome bearing sperm are collected. Rens teaches sampling rates of 500 sperm/second and 2000 sperm/second (column 6). Further, the nozzle allowed for sample rates up to at least 15,000 sperm/sec (column 4, lines 29-31). Rens states that the "high level of performance is beneficial for efficient sperm sorting." Accordingly, it would have been obvious to one of ordinary skill in the art at the time the invention was made to have modified the method of Seidel so

Art Unit: 1634

as to have used sorting rates of about 500 sperm/sec or 1200 sperm/second in order to have allowed for the faster sorting of sperm so as to have provided adequate quantities of sex-sorted samples that could be used for the insemination process.

### ***Double Patenting***

11. The nonstatutory double patenting rejection is based on a judicially created doctrine grounded in public policy (a policy reflected in the statute) so as to prevent the unjustified or improper timewise extension of the "right to exclude" granted by a patent and to prevent possible harassment by multiple assignees. See *In re Goodman*, 11 F.3d 1046, 29 USPQ2d 2010 (Fed. Cir. 1993); *In re Longi*, 759 F.2d 887, 225 USPQ 645 (Fed. Cir. 1985); *In re Van Ornum*, 686 F.2d 937, 214 USPQ 761 (CCPA 1982); *In re Vogel*, 422 F.2d 438, 164 USPQ 619 (CCPA 1970); and, *In re Thorington*, 418 F.2d 528, 163 USPQ 644 (CCPA 1969).

A timely filed terminal disclaimer in compliance with 37 CFR 1.321(c) may be used to overcome an actual or provisional rejection based on a nonstatutory double patenting ground provided the conflicting application or patent is shown to be commonly owned with this application. See 37 CFR 1.130(b).

Effective January 1, 1994, a registered attorney or agent of record may sign a terminal disclaimer. A terminal disclaimer signed by the assignee must fully comply with 37 CFR 3.73(b).

Claims 124-141 are rejected under the judicially created doctrine of obviousness-type double patenting as being unpatentable over claims 1-20 of U.S. Patent 6,071,689 in view of Seidel (1996) or Seidel (1997). Although the conflicting claims are not identical, they are not patentably distinct from each other because the instant claims and the claims of '689 are inclusive of methods for producing a nonhuman mammal wherein the methods comprise creating superovulation in a female mammal to produce at least two eggs; determining the sex of sperm cells from a male mammal and sorting the sperm cells according to sex; inserting at least a portion of the sperm cells into the uterus of said female mammal; and fertilizing a plurality of said eggs to produce multiple sexed embryos. The instant claims and the claims of '689 are further inclusive of

Art Unit: 1634

methods in which the sperm cells are sorted by high speed flow cytometry wherein a sheath fluid is created which contains 2.9% sodium citrate, methods in which the sheath fluid contains a HEPES buffered medium, methods in which sorting is performed at rates above 500 sorts/second and methods in which a low dose of sperm cells is utilized. The claims of '689 do not recite the use of an insemination sample having a low number of sorted sperm that can be used to fertilize a nonhuman mammal at success levels comparable to a typical insemination dosage. However, Seidel (1996) and Seidel (1997) each teach methods for producing bovine mammals comprising sorting sperm cells according to sex using flow cytometry wherein the sperm cells are sorted to purity rates of about 90%, establishing an insemination sample, inserting a low dosage ( $1-2 \times 10^5$  in .1 ml) of sorted sperm cells into the uterine horns of the female bovine after the onset of estrus; and fertilizing the eggs of the bovine so as to produce at least one offspring of the desired sex. The references each teach that insemination with low dose sorted sperm cooled to 5C during shipping occurred at a frequency of about 50%. In view of the teachings in the present specification, this is considered to be a success level comparable to a typical insemination dosage. Accordingly, it would have been obvious to one of ordinary skill in the art at the time the invention was made to have modified the method of '689 so as to have used the low doses of sperm taught by Seidel (1996 or 1997) in order to have provided an effective means for producing bovine of a selected sex.

12. Claims 124-141 are rejected under the judicially created doctrine of obviousness-type double patenting as being unpatentable over claims 1-45 of U.S. Patent 6,524,860

Art Unit: 1634

in view of Seidel (1996) or Seidel (1997). Although the conflicting claims are not identical, they are not patentably distinct from each other because the instant claims and the claims of '860 are inclusive of methods for producing a nonhuman mammal wherein the methods comprise establishing a cell source which supplies cells to be sorted, chemically coordinating a sheath fluid to create a sheath fluid environment for said cells wherein the sheath fluid is coordinated with both the pre-sort and post-sort environment, separating the sperm cells according to sex; inserting at least a portion of the sperm cells into the uterus of a female nonhuman mammal; and fertilizing a plurality of said eggs to produce a nonhuman mammal. The instant claims and the claims of '860 are further inclusive of methods in which the sperm cells are sorted by high speed flow cytometry wherein a sheath fluid is created which contains 2.9% sodium citrate, methods in which the sheath fluid contains a HEPES buffered medium, methods in which sorting is performed at rates above 500 sorts/second, methods in which the sperm are stained using 38uM, methods in which the sperm are collected in wide collection tubes, and methods in which a low dose of sperm cells is utilized. The claims of '860 do not recite the use of an insemination sample having a low number of sorted sperm that can be used to fertilize a nonhuman mammal at success levels comparable to a typical insemination dosage. However, Seidel (1996) and Seidel (1997) each teach methods for producing bovine mammals comprising sorting sperm cells according to sex using flow cytometry wherein the sperm cells are sorted to purity rates of about 90%, establishing an insemination sample, inserting a low dosage ( $1-2 \times 10^5$  in .1 ml) of sorted sperm cells into the uterine horns of the female bovine after the onset of

Art Unit: 1634

estrus; and fertilizing the eggs of the bovine so as to produce at least one offspring of the desired sex. The references each teach that insemination with low dose sorted sperm cooled to 5C during shipping occurred at a frequency of about 50%. In view of the teachings in the present specification, this is considered to be a success level comparable to a typical insemination dosage. Accordingly, it would have been obvious to one of ordinary skill in the art at the time the invention was made to have modified the method of '860 so as to have used the low doses of sperm taught by Seidel (1996 or 1997) in order to have provided an effective means for producing bovine of a selected sex.

13. Claims 124-141 are rejected under the judicially created doctrine of obviousness-type double patenting as being unpatentable over claims 1-18 of U.S. Patent 6,372,422 in view of Seidel (1996) or Seidel (1997). Although the conflicting claims are not identical, they are not patentably distinct from each other because the instant claims and the claims of '422 are inclusive of methods for producing a nonhuman mammal wherein the methods comprise establishing a cell source which supplies cells to be sorted, separating sperm cells according to sex; inserting at least a portion of the sperm cells into the uterus of a female nonhuman mammal that has been superovulated and fertilizing a plurality of said eggs to produce a nonhuman mammal. The instant claims and the claims of '422 are further inclusive of methods in which the sperm cells are sorted by high speed flow cytometry wherein a sheath fluid is created which contains 2.9% sodium citrate, methods in which the sheath fluid contains a HEPES buffered medium, methods in which sorting is performed at rates above 500 or 12000

Art Unit: 1634

sorts/second, methods in which the sperm are collected in wide collection tubes, and methods in which a low dose of sperm cells is utilized. The claims of '422 do not recite the use of an insemination sample having a low number of sorted sperm that can be used to fertilize a nonhuman mammal at success levels comparable to a typical insemination dosage. However, Seidel (1996) and Seidel (1997) each teach methods for producing bovine mammals comprising sorting sperm cells according to sex using flow cytometry wherein the sperm cells are sorted to purity rates of about 90%, establishing an insemination sample, inserting a low dosage ( $1-2 \times 10^5$  in .1 ml) of sorted sperm cells into the uterine horns of the female bovine after the onset of estrus; and fertilizing the eggs of the bovine so as to produce at least one offspring of the desired sex. The references each teach that insemination with low dose sorted sperm cooled to 5C during shipping occurred at a frequency of about 50%. In view of the teachings in the present specification, this is considered to be a success level comparable to a typical insemination dosage. Accordingly, it would have been obvious to one of ordinary skill in the art at the time the invention was made to have modified the method of '422 so as to have used the low doses of sperm taught by Seidel (1996 or 1997) in order to have provided an effective means for producing bovine of a selected sex.

14. Claims 124-141 are provisionally rejected under the judicially created doctrine of obviousness-type double patenting as being unpatentable over claims 1, 2, 5-12, 16-29, 165-184 of copending Application No. 09/582,809. Although the conflicting claims are not identical, they are not patentably distinct from each other because the instant claims

Art Unit: 1634

and the claims of '809 are each inclusive of methods for producing a nonhuman mammal wherein the methods comprise creating superovulation in a female mammal to produce at least two eggs; determining the sex of sperm cells from a male mammal and sorting the sperm cells according to sex; inserting at least a portion of the sperm cells into the uterus of said female mammal; and fertilizing a plurality of said eggs to produce multiple sexed embryos. The instant claims and the claims of '689 are further inclusive of methods in which the sperm cells are sorted by high speed flow cytometry wherein a sheath fluid is created which contains 2.9% sodium citrate, methods in which the sheath fluid contains a HEPES buffered medium, methods in which sorting is performed at rates above 500 sorts/second and methods in which a low dose of sperm cells is utilized. Additionally, the present claims and the claims of '809 recite the use of an insemination sample having a low number of sorted sperm that can be used to fertilize a nonhuman mammal at success levels comparable to a typical insemination dosage.

This is a provisional obviousness-type double patenting rejection because the conflicting claims have not in fact been patented.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to Carla Myers whose telephone number is (571) 272-0747. The examiner can normally be reached on Monday-Thursday from 6:30 AM-5:00 PM. A message may be left on the examiner's voice mail service. If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Gary Benzion, can be reached on (571)-272-0782.

Any inquiry of a general nature or relating to the status of this application or proceeding should be directed to (571) 272-0547.

Patent applicants with problems or questions regarding electronic images that can be viewed in the Patent Application Information Retrieval system (PAIR) can now

Art Unit: 1634

contact the USPTO's Patent Electronic Business Center (Patent EBC) for assistance. Representatives are available to answer your questions daily from 6 am to midnight (EST). The toll free number is (866) 217-9197. When calling please have your application serial or patent number, the type of document you are having an image problem with, the number of pages and the specific nature of the problem. The Patent Electronic Business Center will notify applicants of the resolution of the problem within 5-7 business days. Applicants can also check PAIR to confirm that the problem has been corrected. The USPTO's Patent Electronic Business Center is a complete service center supporting all patent business on the Internet. The USPTO's PAIR system provides Internet-based access to patent application status and history information. It also enables applicants to view the scanned images of their own application file folder(s) as well as general patent information available to the public.

For all other customer support, please call the USPTO Call Center (UCC) at 800-786-9199.
